

<< Only problem 3.1 will be graded. >>

Linear optimization example

Ex. A small startup hardware company is selling smart gadgets. This company has two main products which are smartwatches, and smart TVs sold for 1,200 and 5,000 THB, respectively. The company decides that they will buy a 3D printer to manufacture their products instead of using Chinese factories. After some testing, a printer could produce a maximum of 50 watches or 10 TVs per day. Due to the issues with logistics a total 55 items could be produced per day. For the maintenance issue, at least 3 TVs have to be produced per day. Assuming that the demand for both items is unlimited, the company asks you how many watches and TVs should they produce per single printer to maximize revenue.

To solve this problem, first, we have to formulate this problem as a mathematical program.

To model the program we should :

1. Identifying the decision variable.
2. Identifying the objective.
3. Identifying the constraints.

A mathematical program for this example is :

Decision variable

x_1 : The amount of smartwatches produced per day x_2 : The amount of TVs produced per day

$$\text{Objective : } \max(1200x_1 + 5000x_2)$$

$$\begin{aligned} & \frac{1}{50}x_1 + \frac{1}{10}x_2 \leq 1 \\ \text{s. t.} \quad & x_1 + x_2 \leq 55 \\ & x_2 \geq 3 \\ & x_1, x_2 \geq 0 \end{aligned}$$

After the linear program is modeled, we then convert the program into a standard form.

$$\text{Objective : } \min(-1200x_1 - 5000x_2)$$

$$\begin{aligned} & \frac{1}{50}x_1 + \frac{1}{10}x_2 + x_3 = 1 \\ \text{s. t.} \quad & x_1 + x_2 + x_4 = 55 \\ & x_2 - x_5 = 3 \\ & x_1, x_2, x_3, x_4, x_5 \geq 0 \end{aligned}$$

After the problem is converted into a standard form, we then convert it into a matrix form.

$$\begin{aligned} \min \quad & \mathbf{c}^T \mathbf{x} \\ \text{s.t.} \quad & \mathbf{Ax} = \mathbf{b} \\ & \mathbf{x} \geq 0 \end{aligned}$$

where

$$\mathbf{c} = \begin{bmatrix} -1200 \\ -5000 \\ 0 \\ 0 \\ 0 \end{bmatrix}, \mathbf{A} = \begin{bmatrix} \frac{1}{50} & \frac{1}{10} & 1 & 0 & 0 \\ 1 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & -1 \end{bmatrix}, \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix}, \mathbf{b} = \begin{bmatrix} 1 \\ 55 \\ 3 \end{bmatrix}$$

After the matrix form is obtained, we then feed the matrices into a linear optimization library to solve for an optimal solution and optimal value.

Import library

```
In [1]: from scipy.optimize import linprog
import numpy as np
```

Creating a matrix form of the problem

```
In [2]: c_T = np.array([-1200, -5000, 0, 0, 0])
A = np.array(
    [
        [1/50, 1/10, 1, 0, 0],
        [1, 1, 0, 1, 0],
        [0, 1, 0, 0, -1],
    ]
)
bound = [[0, None], [0, None], [0, None], [0, None], [0, None]] # bound for x
b = [1, 55, 3]
```

Solving the optimization problem

It was found that $\mathbf{x} = [35, 3, 0, 17, 0]$, which means that we should produce 35 watches and 3 TVs per day.

```
In [3]: result = linprog(c=c_T, A_eq=A, b_eq=b, bounds=bound, method='simplex')
print("{}\n\n optimal value is {} \n optimal solution is {}".format(result.fun, result.x, result.message))
```

```

Tips and tricks

You can create an identity matrix by using `np.eye` .

```
In [6]: x = np.eye(5)
print(x)
```

```
[[1.  0.  0.  0.  0.]
 [0.  1.  0.  0.  0.]
 [0.  0.  1.  0.  0.]
 [0.  0.  0.  1.  0.]
 [0.  0.  0.  0.  1.]]
```

```
In [7]: y = np.zeros((8, 8))
x = np.eye(5)
y[2: 7, 2: 7] =x
print(y)
```

```
[[0.  0.  0.  0.  0.  0.  0.  0.]
 [0.  0.  0.  0.  0.  0.  0.  0.]
 [0.  0.  1.  0.  0.  0.  0.  0.]
 [0.  0.  0.  1.  0.  0.  0.  0.]
 [0.  0.  0.  0.  1.  0.  0.  0.]
 [0.  0.  0.  0.  0.  1.  0.  0.]
 [0.  0.  0.  0.  0.  0.  1.  0.]
 [0.  0.  0.  0.  0.  0.  0.  0.]]
```

You can also index data diagonally.

```
In [8]: a = np.array([3, 2, 1])
print(np.diag(a))
```

```
[[3 0 0]
 [0 2 0]
 [0 0 1]]
```

```
In [9]: y = np.zeros((6, 6))
y[2: 5, 2: 5] =np.diag(a)
print(y)
```

```

[[0. 0. 0. 0. 0. 0.]
 [0. 0. 0. 0. 0. 0.]
 [0. 0. 3. 0. 0. 0.]
 [0. 0. 0. 2. 0. 0.]
 [0. 0. 0. 0. 1. 0.]
 [0. 0. 0. 0. 0. 0.]]

```

```

In [10]: y = np.zeros((6, 6))
         di = np.diag_indices(len(a))
         y[di] = a
         print(y)
         y[di[0], di[1] + 1] = a * 2
         print(y)

```

```

[[3. 0. 0. 0. 0. 0.]
 [0. 2. 0. 0. 0. 0.]
 [0. 0. 1. 0. 0. 0.]
 [0. 0. 0. 0. 0. 0.]
 [0. 0. 0. 0. 0. 0.]
 [0. 0. 0. 0. 0. 0.]]
[[3. 6. 0. 0. 0. 0.]

Problem 1 : Skill Check

Solve the following program :

$$\text{Objective : } \max(3x + 4y)$$

$$\begin{aligned}
 & x + 2y \leq 7 \\
 & s.t. \quad 3x - y \geq 0 \\
 & \quad \quad x - y \leq 2 \\
 & \quad \quad x, y \geq 0
 \end{aligned}$$

\therefore Standard form :

$$\text{Objective : } \min(-3x - 4y)$$

$$\begin{aligned}
 & x + 2y + s_1 = 7 \\
 & 3x - y - e_1 = 0 \\
 & x - y + s_2 = 2 \\
 & x, y, s_1, s_2, e_1 \geq 0
 \end{aligned}$$

$$\begin{aligned} \min \quad & \mathbf{c}^T \mathbf{x} \\ \text{s.t.} \quad & \mathbf{Ax} = \mathbf{b} \\ & \mathbf{x} \geq 0 \end{aligned}$$

where

$$\mathbf{c} = \begin{bmatrix} -3 \\ -4 \\ 0 \\ 0 \\ 0 \end{bmatrix}, \mathbf{A} = \begin{bmatrix} 1 & 2 & 1 & 0 & 0 \\ 3 & -1 & 0 & 0 & -1 \\ 1 & -1 & 0 & 1 & 0 \end{bmatrix}, \mathbf{x} = \begin{bmatrix} x \\ y \\ s_1 \\ s_2 \\ e_1 \end{bmatrix}, \mathbf{b} = \begin{bmatrix} 7 \\ 0 \\ 2 \end{bmatrix}$$

```
In [12]: c_T = np.array([-3, -4, 0, 0, 0])
A = np.array(

Problem 1.2 :

Solve problem 1 by using a graphical method and draw an isoprofit line. Does the obtained solution the same as the one we get in problem 1? You can solve this problem on your tablet/paper or use a plotting library.

```
In [13]: # basic matplotlib command
import matplotlib.pyplot as plt
x = np.linspace(0, 1000, 100)
y = 2 * x + 1
y2 = -x + 49

min_y, max_y = -10000, 10000
```

```

plt.figure(figsize = (5, 5))
plt.xlim(0, 100)
plt.ylim(0, 100)
plt.title('y = 2x + 1, y = -x + 49')
plt.plot(x, y, color = 'green', label = 'y = 2x+1')
plt.fill_between(x, y, min_y, color = 'red', alpha = 0.3, label = 'area u
plt.fill_between(x, y, max_y, color = 'blue', alpha = 0.3, label = 'area

plt.plot(x, y2, color = 'orange', label = 'y = -x+49')
plt.fill_between(x, y2, min_y, color = 'yellow', alpha = 1)

plt.scatter(16, 33, s = 100, color = 'purple', label = 'intersection poi
plt.legend()
plt.grid(color = 'black')

plt.show()

```

Problem 2 : Hamtaro factory

After Hamtaro finished planting the sunflower field, he then aims to open the Hamtaro factory, selling sunflower snacks to the fellow hamsters. However, the harvested sunflower seeds have different grades, which leads to different nutrition values. Nutrition values for each grade are shown in the table below. To sell the snack at the market, the HFA (Hamster Food Administration) states that the snack they produce must contain at least 60% protein and no more than 5% fat. To minimize the ingredient cost, how should Hamtaro mix the sunflower seeds to pass the HFA approval? Formulate the problem as a linear program and solve for an optimal solution.

sunflower seed grade	% protein	% fat	cost per g (THB)
terrible	25	10	0.01
low	40	7	0.3
medium	70	4	0.7
high	90	1	1.2

Decision Variables:

- x_1 = grams of **terrible** grade sunflower seeds.
- x_2 = grams of **low** grade sunflower seeds.
- x_3 = grams of **medium** grade sunflower seeds.
- x_4 = grams of **high** grade sunflower seeds.

Objective Function:

minimize the cost

$$\min(0.01x_1 + 0.3x_2 + 0.7x_3 + 1.2x_4)$$

Constraints:

at least 60% protein

$$0.25x_1 + 0.40x_2 + 0.70x_3 + 0.90x_4 \geq 0.60(x_1 + x_2 + x_3 + x_4)$$

no more than 5% fat

$$0.10x_1 + 0.07x_2 + 0.04x_3 + 0.01x_4 \leq 0.05(x_1 + x_2 + x_3 + x_4)$$

$$x_1, x_2, x_3, x_4 \geq 0$$

Standard Form:

$$\min(0.01x_1 + 0.3x_2 + 0.7x_3 + 1.2x_4)$$

$$-0.35x_1 - 0.20x_2 + 0.10x_3 + 0.30x_4 - e_1 = 0$$

$$0.05x_1 + 0.02x_2 - 0.01x_3 - 0.04x_4 + s_1 = 0$$

$$x_1, x_2, x_3, x_4, e_1, s_1 \geq 0$$

$$\begin{array}{ll} \min & \mathbf{c}^T \mathbf{x} \\ \text{s.t.} & \mathbf{Ax} = \mathbf{b} \\ & \mathbf{x} \geq 0 \end{array}$$

Problem 3.1 : Storage server management

- A company is running a video analytic system.
- To store the analyzed videos, the company has 10 local storage servers to store the data, of which each of them could store 24 TB per server.
- Recently, the company finds out that the servers they have will not be adequate in the recent future.
- Therefore, the company has to figure out a plan to scale up its resource.
-

- The CTO has come up with two solutions, which are buying new storage servers, and using a cloud storage service called 'SWA S3'.
- The cloud storage service charges 690 THB/TB per month.
- On the other hand, buying a new server costs 40,000 THB, but it could be used for a very long time.
-
- After several discussions, the company has projected the amount of storage required for each month.
- The projected data is shown in the table below.
- To minimize the ***cost***, what should the company do to store the data?
Formulate the problem as a linear program and solve for an optimal solution.

Note 1 : The optimal solution does not have to be an integer. Note 2 : The company could buy new servers at any month.

Month	1	2	3	4	5	6	7	8	
Estimated amount of storage required (TB)	140	200	300	1000	1400	500	600	900	700

Parameters:

- Cloud: 690 THB/TB per month
- Server Capacity: 24 TB
- Server Cost: 40,000 THB

Decision Variables:

t is month for t = 1,2,3,...,8

- x_t = TB of cloud data in month t
- y_t = Amount of new sever bought in month t

Objective Function: minimize cost

cost in each month = cloud data + new bought server

$$\min \left[\sum_{t=1}^8 (690 * x_t + 40,000 * y_t) \right]$$

Constraints:

Storage requirement in each month

$$\begin{array}{ll}
240 + 24 * (y_1) & +x_1 \geq 140 \\
240 + 24 * (y_1 + y_2) & +x_2 \geq 200 \\
240 + 24 * (y_1 + y_2 + y_3) & +x_3 \geq 300 \\
240 + 24 * (y_1 + y_2 + y_3 + y_4) & +x_4 \geq 1,000 \\
240 + 24 * (y_1 + y_2 + y_3 + y_4 + y_5) & +x_5 \geq 1,400 \\
240 + 24 * (y_1 + y_2 + y_3 + y_4 + y_5 + y_6) & +x_6 \geq 500 \\
240 + 24 * (y_1 + y_2 + y_3 + y_4 + y_5 + y_6 + y_7) & +x_7 \geq 600 \\
240 + 24 * (y_1 + y_2 + y_3 + y_4 + y_5 + y_6 + y_7 + y_8) & +x_8 \geq 900
\end{array}$$

$$x_t, y_t \geq 0 \quad ; \quad t = 1, 2, 3, \dots, 8$$

(from Note 1 : The optimal solution does not have to be an integer. not necessary for

$$y_t \in \mathbb{Z})$$

Standard Form:

$$\text{Objective :} \quad \min \left[\sum_{t=1}^8 (690 * x_t + 40,000 * y_t) \right]$$

$$24 * (y_1) + x_1 - e_1 = -100$$

$$24 * (y_1 + y_2) + x_2 - e_2 = -40$$

$$24 * (y_1 + y_2 + y_3) + x_3 - e_3 = 60$$

$$24 * (y_1 + y_2 + y_3 + y_4) + x_4 - e_4 = 760$$

$$24 * (y_1 + y_2 + y_3 + y_4 + y_5) + x_5 - e_5 = 1,160$$

$$24 * (y_1 + y_2 + y_3 + y_4 + y_5 + y_6) + x_6 - e_6 = 260$$

$$24 * (y_1 + y_2 + y_3 + y_4 + y_5 + y_6 + y_7) + x_7 - e_7 = 360$$

$$24 * (y_1 + y_2 + y_3 + y_4 + y_5 + y_6 + y_7 + y_8) + x_8 - e_8 = 660$$

$$x_t, y_t, e_t \geq 0 \quad ; \quad t = 1, 2, 3, \dots, 8$$

$$\begin{array}{ll}
\min & \mathbf{c}^T \mathbf{x} \\
\text{s.t.} & \mathbf{Ax} = \mathbf{b} \\
& \mathbf{x} \geq 0
\end{array}$$

Conclusion:

optimal value/minimum cost = 1,514,000

Month	1	2	3	4	5	6	7	8
Cloud storage	0	0	0	100	500	0	0	0
Amount new buy sever	0	0	2.5	25	0	0	0	0

(from Note 1 : The optimal solution does not have to be an integer.)

Problem 3.2

From problem 3. Would the optimal solution change if the company has to pay 2,000 THB maintenance fee per month for each local storage server they have?

In [16]: **pass**

Problem 4 : Task assignment

A data center company has a lot of servers to be maintained. Thus, the maintainers are required 24/7. To maintain the servers, the company has employed four technicians, of which one of them is a senior. Each technician has to work at least 40 hours per week, except for the senior one, which works exactly 36 hours per week. The wage is paid hourly, and every technician has different wages and availability. The maintenance is performed with exactly one person on duty. How should the company assign each person to be on duty to minimize the maintenance cost? Formulate the problem as a linear program and solve for an optimal solution.

Technician	Wage per hour(weekday)	Wage per hour(weekend)	Maximum hours of availability
------------	------------------------	------------------------	-------------------------------

			Mon.	Tue.	Wed.	Thurs.	Fri.	Sat.
Technician A	70	80	12	10	12	0	8	8
Technician B	70	80	12	10	0	8	8	4
Technician C	80	75	0	10	8	8	0	10
Senior technician D	160	200	24	0	24	24	24	24

In [17]: **pass**

Problem 5 : Courier service

A company named "Curry" provides courier services to the customer. In town X, 10 customers are using this company's service. To satisfy the demand in this town, the company has placed the courier office as a hub for the couriers to collect customers' packages. However, only a limited amount of packages could be stockpiled in each office. The company has to pay the couriers 10 THB per kg per distance they have traveled in kilometer. Moreover, the package could be partially collected (divisible), i.e., a courier from office A and C could collect 200 kg, 300 kg package from customer 1. How should this company plan to send the couriers to collect the package such that the package collection cost is minimized? The amount of packages to be collected for each customer is shown in Table 2.1. The size of each package storage is shown in Table 2.2. The distance from the courier office to each customer is shown in Table 2.3. Formulate the problem as a linear program and solve for an optimal solution.

Note : The optimal solution does not have to be an integer.

Table 2.1. Amount of packages to be collected for each customer.

Customer	1	2	3	4	5	6	7	8	9	10
Amount of packages to be collected (kg)	500	200	1000	2000	150	20	350	250	375	1

Table 2.2. The size of package storage for each office.

Office	Storage size (kg)
A	1500
B	1000
C	4000

Table 2.3. Distance from the office to each household (km)

From / to	1	2	3	4	5	6	7	8	9	10
A	4	3	8	1	2	1	3	2	4	4
B	3	1	1	8	3	4	5	7	9	8
C	8	6	5	3	1	6	7	2	7	5

In [18]: **pass**

Problem 6: VM placement

A startup company is provisioning virtual machines (VM) for cloud computing. Currently, the company offers three types of instances, which are a small, medium, and large instance. The detail for each type of instance is shown in the table below. To host the VMs, the company has a large number of servers to provide its service. All of the servers they possessed have 8 CPUs core. Recently, the company has found a new customer to use their service. The customer want to host 20 small, 9 medium, and 5 large instances for their company. Moreover, the customer also demands that only they could access the provided server, i.e., the company could not use the leftover CPUs to serve other customers despite having 2 CPUs left. How many servers should the company allocate to serve this customer? Formulate the problem as a linear program and solve for an optimal solution.

Instance type	Number of CPUs provided
small	2 CPUs
medium	3 CPUs
large	4 CPUs

Note : The optimal solution does not have to be an integer. **Hint :** How many way could we fit the instances into a single server?

In [19]: **pass**

Problem 7: Linear binary classification model (Maximal Margin Classifier)

This problem will introduce you to a basic machine learning classification algorithm. Let's say that we have the dataset $D = \{(x_0, y_0), (x_1, y_1), \dots, (x_n, y_n)\}$. Each element in D is a datapoint x_i in a form of tuple (x_0, x_1) which belong to the class $y_i \in \{-1, 1\}$. Machine learning algorithm aims to represent the dataset D using sets of parameter θ . For classification task, we use machine learning algorithm to correctly classify the class y given the datapoint x .

In this problem, we use a linear line $\theta_0 x_0 + \theta_1 x_1 + \theta_2 = 0$ as a classifier. The datapoints above and below the line will be classified as class 1 (positive) and -1 (negative) respectively. The objective of this problem is to find the parameters of the

linear classifier θ given D by formulating the problem as a linear program. A figure below demonstrates that the line with the parameter $(\theta_0, \theta_1, \theta_2) = (1.5, 1, -5)$, i.e., $1.5x_0 + x_1 - 5 = 0$, could separate the data into two classes.

```
In [20]: import matplotlib.pyplot as plt
```

```
In [21]: class_a = np.random.randn(10, 2)* 0.5 # generate class -1 data
class_b = np.random.randn(10, 2) * 0.5 + 5# generate class 1 data
```

```
In [22]: print(class_a[0]) # example of datapoint
```

```
[0.26991793 0.12773861]
```

```
In [23]: def generate_decision_boundary(theta_0, theta_1, theta_2, xmin = -10, ym
...
    Input : Parameter theta_0, theta_1, theta_2 of a linear classifier
    Output : Decision boundary ( 1 is positive, -1 is negative, 0 is sepe
...
    x_0, x_1 = np.meshgrid(np.arange(xmin, xmax, h), np.arange(ymin, ymax,
    prediction = theta_0 * x_0 + theta_1 * x_1 + theta_2
    prediction[prediction > 0] = 1
    prediction[prediction < 0] = -1
    return (x_0, x_1, prediction)

theta_0 = 1.5
theta_1 = 1
theta_2 = -5
decision_boundary = generate_decision_boundary(theta_0, theta_1, theta_2)
```

```
In [24]: plt.figure(figsize = (5, 5))
plt.xlim(-4.5, 9)
plt.ylim (-4.5, 9)

plt.scatter(class_a[:, 0], class_a[:, 1], color = 'red', label = 'class -
plt.scatter(class_b[:, 0], class_b[:, 1], color = 'green', label = 'class
plt.contourf(decision_boundary[0], decision_boundary[1], decision_boundar
plt.xlabel('x_0')
plt.ylabel('x_1')
plt.title('green area is  $1.5x_0 + x_1 - 5 > 0$ , red area is  $1.5x_0 + x_1 -$ 
plt.legend()
plt.show()
```

green area is $1.5x_0 + x_1 - 5 > 0$, red area is $1.5x_0 + x_1 - 5 < 0$

As you can see, the line $\theta_0 x_0 + \theta_1 x_1 + \theta_2 = 0$ could separate the data into two classes by constraining x_i which has the value of $\theta_0 x_{i,0} + \theta_1 x_{i,1} + \theta_2 > 0$ into a positive class ($y_i = 1$) and $\theta_0 x_{i,0} + \theta_1 x_{i,1} + \theta_2 < 0$ into a negative class ($y_i = -1$). Therefore, the value of θ could be optimized by constraining the line to satisfy the condition of every datapoint w.r.t. its class, which results in the mathematical program shown below.

Objective : –

$$\begin{aligned}
 & \theta_0 x_{i,0} + \theta_1 x_{i,1} + \theta_2 > 0 \\
 & \theta_0 x_{j,0} + \theta_1 x_{j,1} + \theta_2 < 0 \\
 \text{s. t. } & \forall i, y_i = 1 \\
 & \forall j, y_j = -1
 \end{aligned}$$

The program could also be written in a form of:

Objective : –

$$\text{s. t. } \forall i, y_i (\theta_0 x_{i,0} + \theta_1 x_{i,1} + \theta_2) > 0$$

The program above could return a feasible solution yet the wellness of the optimized value is not defined. For example, H_2 and H_3 in the image below are both acceptable solutions using the program above. However, H_3 might be a preferred solution.

Image source:

https://upload.wikimedia.org/wikipedia/commons/b/b5/Svm_separating_hyperplanes_%2

Thus, we introduce the margin ϵ to define the wellness of the program. The margin is the shortest distance from the hyperplane to the closest datapoint. Maximizing ϵ would result in the line which has the largest separation between the two classes (maximum margin). As a result, the program becomes:

$$\text{Objective : } \max(\epsilon)$$

$$\theta_0 x_{i,0} + \theta_1 x_{i,1} + \theta_2 \geq \epsilon$$

$$\theta_0 x_{j,0} + \theta_1 x_{j,1} + \theta_2 \leq -\epsilon$$

$$\begin{aligned} \text{s. t.} \quad & \forall i, y_i = 1 \\ & \forall j, y_j = -1 \\ & \theta_0, \theta_1 \in [-1, 1] \end{aligned}$$

The program could also be written in a form of:

$$\text{Objective : } \max(\epsilon)$$

$$\begin{aligned} \text{s. t.} \quad & \forall i, y_i (\theta_0 x_{i,0} + \theta_1 x_{i,1} + \theta_2) \geq \epsilon \\ & \theta_0, \theta_1 \in [-1, 1] \end{aligned}$$

θ_0, θ_1 are both bounded to $[-1, 1]$ to prevent unbounded solution.

Note: This is a simplified version of a linear support vector machine and many details are omitted. You can read more at https://en.wikipedia.org/wiki/Support-vector_machine#Linear_SVM if interested.

Problem 7.1

Convert the mathematical program above into a linear program. Then, use the converted program to solve for the line separating the datapoints below. **Do not forget to visualize the solved line.**

```
In [25]: class_a = np.array([[np.random.uniform(2.1, 3), np.random.uniform(2.3, 4)
class_b = np.array([[np.random.uniform(-1, 2), np.random.uniform(0, 2.2)]
print(class_a.shape)
```

```
(20, 2)
```

```
In [26]: plt.figure(figsize = (5, 5))
plt.scatter(class_a[:, 0], class_a[:, 1], color = 'red', label = 'class -
```

```
plt.scatter(class_b[:, 0], class_b[:, 1], color = 'green', label = 'class 1')
plt.legend()
plt.show()
```

In [27]: `pass`

Problem 7.2

Given the datapoints below, repeat 7.1 and observe the result. What is happening to the solution and why does this happen?

```
In [28]: class_a = np.random.uniform(0, 2, (20, 2)) # class -1 data
         class_b = np.random.uniform(0.5, 3, (20, 2)) # class 1 data
```

```
In [29]: plt.figure(figsize = (5, 5))
         plt.scatter(class_a[:, 0], class_a[:, 1], color = 'red', label = 'class -1')
         plt.scatter(class_b[:, 0], class_b[:, 1], color = 'green', label = 'class 1')
         plt.legend()
         plt.show()
```

In [30]: `pass`
